Isolated by Caste: Neighbourhood-Scale Residential Segregation in Indian Metros

Naveen Bharathi, Deepak Malghan and Andaleeb Rahman
It is the policy of Cornell University actively to support equality of educational and employment opportunity. No person shall be denied admission to any educational program or activity or be denied employment on the basis of any legally prohibited discrimination involving, but not limited to, such factors as race, color, creed, religion, national or ethnic origin, sex, age or handicap. The University is committed to the maintenance of affirmative action programs which will assure the continuation of such equality of opportunity.
Abstract: We present the first ever neighbourhood-scale portrait of caste-based residential segregation in Indian cities. Residential segregation studies in Indian cities have relied on ward-level data that we demonstrate in this paper to be very heterogeneous themselves. Using 2011 enumeration block (EB) level census data for five major cities in India – Bengaluru, Chennai, Delhi, Kolkata, and Mumbai – we show how patterns of caste-based urban residential segregation operate in contemporary India. We also present the first visual snapshot of caste-based residential segregation in an Indian city using georeferenced EB level data for Bengaluru. Besides implications for policy, our analysis also points to the need for publicly available, geospatially-linked neighborhood-scale census data that includes data on economic class.

Keywords: Residential Segregation; Urban; Caste
1. Introduction

Caste in India is one of the most complex and rigid social structures whose basic characteristics include complex network of hierarchies, segmentation, and segregation (Ghurye, 1969). An individual’s caste marker is closely correlated with both class and power (Béteille, 1965). Spatial segregation and discrimination have been one of the basic aspects of the caste system (A. R. Desai, 1994). Many founding fathers of the Indian Constitution including most famously, Ambedkar, advocated greater urban migration for Dalits (previously known as ‘untouchables’, and administratively referred to as the ‘Scheduled Castes’) as a solution to escape the most egregious consequences of caste. The structure of caste in the process of urbanization is expected to fuse with class blurring some of the most pernicious consequences of caste-based stratification. Andre Beteille (1997) has argued that in Urban India, the social status is determined by the markers of class (income, wealth, and education) rather than caste. It has been assumed that that caste cannot control the organization of spatial environment of a city as it does in a village (Swallow, 1982). Contemporary Dalit intellectuals continue to believe that as India urbanizes, ‘caste is losing, and will continue to lose, its strength’ (C. B. Prasad, 2010). Historically, communities have migrated to cities to ‘escape’ caste hegemony in the villages – Mahars (an ‘untouchable’ caste) migrated to cities like Bombay and Nagpur in large numbers at the beginning of the 20th century (Rao, 2009). The population of Dalits in Urban India saw an increase of 40 percent in the decade 2001-2011.¹ In contemporary India, caste continues to have a major impact on various socio-economic outcomes like education, health, labor markets and electoral politics (Borooah, 2010; Kothari, 1995; Nambissan, 2009; S. Thorat & Neuman, 2012). Rights, access, citizenship and privileges of an individual are often tied to his or her membership of a particular caste (Deshpande, 2000, 2001; Thorat, Banerjee, Mishra, & Rizvi, 2015; Thorat & Neuman, 2012).

One of the primary aspects of caste system is residential segregation (Ghurye, 1969). Even in contemporary rural India, residential areas are divided along caste lines. Castes lower in the hierarchy mostly live on the outskirts of the village; and inside the village proper, different quarters are strictly segregated along caste lines. Such arrangement also regulates castes’ access to public goods such as village well, grazing fields, etc. The social distance and hierarchies of various castes are reflected in the spatial segregation of residential localities in a settlement (Mukherjee, 1968). Caste-based residential segregation further contributes to widening of social and cognitive distances between caste groups. Social hierarchies are reinforced by spatial isolation and separation. Greater the segregation – voluntarily or involuntarily -- lesser is the likelihood of interaction between communities. Muslims in Indian cities are a classic example of such isolation and ghettoization (Gayer & Jaffrelot, 2012). The possibilities of close relationships on the basis of social equality are greatly reduced. Instead, contacts tend to be formalized, confined principally to the market place or work place (Hazlehurst, 1970). Such contacts are usually marginal, and devoid of any sustaining social value. People who work together or who have contacts of a strictly economic character may live in entirely different social and ecological worlds (Gist & Fava, 1970).

There are very few formal quantitative characterization of patterns of urban segregation in India. Given data limitations that we describe here, ethnographic accounts have dominated the literature (for example, Gist, 1957; Hazlehurst, 1970; Lynch, 1967). Census of India reports caste information in three broad aggregate categories – SC, ST, and Others, and these broad aggregates were publicly reported at the ward level. Thus the unit of analysis is limited in both spatial resolution as well as ethnic resolution (Dupont, 2004; Sidhwan, 2015; Vithayathil & Singh, 2012). As these studies show, there are serious limitations of using ward level census data to study caste segregation in a city. The average population in an urban ward can vary from 1500 to 6000 for small statutory

¹ Source: Census of India Abstract, 2011. For earlier periods, see Teltumbde (2016)
towns and municipalities. In larger metropolitan cities, ward size may vary from 30000 to 200,000 (R. N. Prasad, 2006). Hence for studying neighborhood level segregation, the ward is scarcely the most useful spatial unit of analysis. A census enumeration block (or sub-block) has around 100-125 households with a population of 650-700.\(^2\) Figures 1 and 2 illustrate the limitations of using ward level data as a proxy for neighbourhood residential segregation. Even without accounting for social groups, these figures show substantive intra-ward variation in distribution of people in Bengaluru. The maps show how the EBs within a ward are heterogeneous even in terms of aggregate population numbers.

A necessary preliminary for any formal analysis of neighbourhood-scale residential segregation is a plausible definition of what constitutes a neighborhood unit. There is no universal definition of a ‘neighborhood unit’, and urbanists have used diverse approaches to define the scale of an ideal neighborhood. Every individual living in an urban area can perceive the scale of the neighborhood very differently (Chaskin, 1994; Lee & Campbell, 1997; Logan & Collver, 1983). Unless very well defined by natural or built boundaries such as roads, lakes, gardens etc. the size and scale of the neighborhood mostly depends on the perception of the individual inhabitant. But if we must study residential segregation, it becomes important the boundaries of the neighborhood are well defined and are comparable. Studies on segregation in US cities have typically used Census tract as the preferred spatial unit of analysis (Iceland & Weinberg, 2002; Massey & Denton, 1987). Census tracts have approximately 4000 people living in them and the boundaries of a census tract have been stable over many decennial censuses to permit historical time-series analysis. Indian ward and census enumeration block boundaries are constantly redrawn making any longitudinal study of urban areas impossible. There is no perfect definition of a neighborhood and segregation studies are often restricted by the administrative data available which may, or may not reflect the neighborhood as perceived by the inhabitants in a city.

http://rural.nic.in/sites/default/files/Supervisory%20Manual%20June%202012%20%28English%29_1.pdf
Even if a ward is diverse in terms of caste composition, the communities might be highly segregated within a ward. For example, in Bengaluru upper caste neighborhoods are abutted by highly dense lower caste settlements. Thus even when spatially proximate, the social distance between these neighborhoods can be very high (Shaw, 2012). Clustering can happen even at a micro street-level, with households from two different castes occupying adjoining streets. Hence, the unit of analysis must be still smaller – say a street. Given the compact spatial spread on an urban census enumeration block, we argue that that they represent a good proxy for neighbourhoods. Of the five cities that we study, we are able to visually test this assumption in the case of Bengaluru where we use geo-referenced enumeration block level data. For the four other cities, we use enumeration block data that is not geo-referenced. To the best of our knowledge, this paper is the first ever attempt to use enumeration block data (released in 2015) to study caste-based residential segregation in India.
This paper shows why the usage of ward as a unit to study spatial segregation grossly understates the true extent of caste-based residential segregation in urban India. The remainder of the paper is organized as follows. The next section provides a brief overview of various studies on spatial segregation in India. In the following section, we discuss our data and the methodology, and also more rigorously defend the census enumeration block as the appropriate spatial unit of analysis for studying residential segregation. Following a analytical discussion of our key results, we present India’s first ever visual map of residential segregation using enumeration block map for the city of Bengaluru, before concluding with object lessons for research as well as policy.

2. Why Study Residential Segregation?

Residential segregation refers to spatial separation of different social-economic groups in a given geographical area. People can be residentially segregated along various dimensions – class, race, language, religion etc. Data on residential segregation along caste lines when combined with data on levels of urbanization, and rural-urban migration patterns can help empirically test a widely-held normative belief that urbanization reduces caste based spatial segregation.

The patterns and characteristics of residential segregation in US and European settlements have been extensively studied – earliest studies on the subject date back to the so-called Chicago School (see for example, Burgess, 1928; Park, Burgess, McKenzie, & Wirth, 1925). The segregation of African Americans and other ethnic minority groups in US cities have been a subject of continuous study since. Any segregation, as research on race in US cities shows, is detrimental to economic growth, societal equity, and economic mobility leading to alienation of communities (Cutler & Glaeser, 1997). Communities with more diversity have fewer crime rates compared to homogeneous communities (Graif & Sampson, 2009; Letki, 2008; Portes & Vickstrom, 2015). A study by Chetty, Hendren, Kline, & Saez (2014) has shown that the neighborhood where one grows up has a major impact on his/her lifetime earnings and success later in life. The research found that low residential segregation results in upward social and economic mobility. Residential segregation aggravates the
existing socio-economic inequality. Neighborhoods shape the lives of the children and the youth. Children growing in highly segregated poor neighborhoods are more susceptible to failure and emotionally vulnerable (Harding, 2003). Neighborhood diversity can have a positive impact on these disadvantaged groups by exposing them to mainstream role models and successful individuals (Wilson, 1987). Ludwig et al. (2013) prove that moving to a better neighborhood had a positive impact on the physical and mental health of the disadvantaged households. Putnam (2007) in fact counters his own theory by arguing that the negative effects of diversity are just temporary, and the positive aspects of diversity will takeover in the long run.

Segregation also results in ghettoization of minority and poor groups and this aspect of stratification spills over to next generations (Morgan, 1984). In times of communal violence, it becomes easy to target individuals of a particular group or community. Los Angeles riots of 1992, for example, was due to highly segregated residential neighborhoods with ‘unequal social and political endowments and economic niches’ (Morrison, Lowry, & Rand Corporation, 1993). Segregation of residential areas on caste/race lines has resulted in concentration of poverty (for example slums). Residential segregation keeps intact the existing social and economic divisions and over time, can undermine prosperity (Carr & Kutty, 2008). Black families who moved to predominantly white neighborhoods achieved significant amount socio-educational gains (Rubinowitz & Rosenbaum, 2000). Ihlanfeldt & Scafidi (2002) conclude that people living in heterogeneous neighborhoods are less discriminative towards people belonging to other races and ethnic groups.

In Indian cities, individuals are routinely denied access to housing of their choice based on their caste identity (Thorat et al., 2015). Thomas Schelling (1971) in his seminal paper showed that this simple act of denial or a small preference for one's neighbors to be of the same caste/race could lead to total segregation. Such preferences directly or indirectly give rise to highly segregated neighborhoods and localities based on caste and often the distribution of public services and goods are associated with neighborhood characteristics (Miklian & Sahoo, 2016).

Caste Based Segregation in Urban India

The received wisdom is that the sense of relative anonymity provided by urban areas will result in lower levels of caste-based segregation of space. However, the empirical reality of urban India does not live up to this received wisdom – at least not in any whole measure. Historically, Indian cities have also been segregated along caste lines. According to Karim (1956), the city population in pre-British India was largely segregated geographically by religion, caste and sub-caste, and by occupational and regional groups forming social islands. These social units developed such exclusiveness that the groups constituted cities within cities. Gist (1957) in his study of Bengaluru documents caste and religion based residential segregation. Studies of Jatav thoks and mobollas of Agra by Lynch (1967) and of Lucknow rickshawallas by Gould (1965) show caste as an important and even a predominant factor in the organization of urban neighborhoods. Similarly, Hazlehurst (1970) in his study of Puranapur in Haryana finds that while public spaces like markets showed a mixture of castes, residential neighborhoods were highly segregated along caste lines. Mehta (1969) in his study of Pune demonstrates that urbanization, industrialization or modernization had vitally no effect on residential segregation based on caste, religion or ethnicity. In independent India, a wide majority of communal violence incidents is associated with urban centres. Hansen (2001) in his study of the rise of Shiv Sena in Mumbai documents how the bonds of caste and religion that got transplanted from a village, hardened in an urban setting.

In the early years of the Indian republic, Nehruvian industrial socialism was seen as one of the pathways out of the limitations of narrow parochial identities such as caste, language and religion. The expectation was that over a period of time, caste would cease being a hermetically sealed institution in its urban avatar, and that caste would eventually merge into class. But does industrialization, economic
growth and urbanization actually dilute the strong communal and kinship bonds of caste? While robust and systematic empirical evidence is scant, anecdotal accounts suggest that the Indian caste system, rather than collapsing to class has instead adapted even while preserving its essential features. Economic liberalization in the 1990s prompted the Indian cities to remodel themselves along post-industrial globalized metropolises. Economic liberalization changed how one looked at Indian cities - at least, at the superficial level it seemed that there might be a structural change in operations of class and caste relations. Caste was irrelevant in a globalized setting and influence of traditional caste was apparently being eroded by ‘forces of urbanism, secularization, and consumerism’ (D’Mello & Sahay, 2008). In a city which is dominated by private sector – where individual agency, knowledge and competence create meritocratic hierarchies, it was argued that caste based ties become irrelevant. But in personal spaces caste continued to hold sway and its influence undiminished (D’Mello & Sahay, 2008). Available empirical evidence suggests that India’s embrace of the market economy has not made the expected dent in the operation of caste. For example, Barbara Harriss-White’s (2003) work on rural Tamil Nadu demonstrates that India’s embrace of the market economy has not reduced caste based inequalities. Desai and Dubey (2011) in their nationwide study on caste based inequalities show that early urbanization benefitted privileged upper caste groups. While in metropolitan areas the associated structures of discrimination is somewhat moderated, caste disparities did not structurally disappear with urbanization. The same study demonstrates that caste inequalities are low in developed villages and metropolitan cities compared to smaller cities. Miklian and Sahoo (2016) in their study of three Indian cities note that rather than being “melting pots” and places for upward social mobility, Indian cities stubbornly mirror India’s rural social and economic realities’ and rural social structures are often repeated in urban settings. They also found out that Muslims and Dalits found it hard to escape the inherent discrimination in a metropolis and thereby pushing them to live in fringes and in segregated neighborhoods. Ahuja and Osterman (2015) while studying Indian marriage market observe that the grasp of caste in urban areas is low as compared to rural areas as urban areas provide ‘relative anonymity’ from the practices of purity and pollution.

Vithayathil & Singh (2012) used ward-level data from the 2001 census to show that in the seven largest metro cities of India ‘residential segregation by caste was greater than the degree of residential segregation by socio-economic status.’ Given the large size of wards in metro cities, their results likely underestimates the true extent of caste-based segregation. In this paper, we show that a ward is too large to be a neighborhood – especially in the metros where a ward can be as large as a small town. The real import of caste-based segregation can only be studied at a higher spatial resolution that better approximates a neighbourhood.

3. Data and Methodology

This paper uses data from Census of India 2011 which gives total population (Male and Female) and Scheduled Caste and Tribe population for every enumeration block within a urban ward. As discussed in the introductory section, a census enumeration block (or sub-block) has around 100-125 households with a population of 650-700. In this paper we present data for four traditional metropolitan cities of India – Chennai, Delhi, Kolkata and Mumbai along with Bengaluru. Inset tables in Figure 3 list the mean and median ward and block size for these five major urban cities. Clearly, ward sizes vary across cities making them incomparable, but the mean block level size is consistent across all the cities. Figure 3 gives Empirical cumulative distribution function (ECDF) plots for block and ward population sizes for all the five cities that we study in this paper. ECDF block population

3 Appendix 1, Table A-12 of the Census Abstract, 2011.
plots of different cities overlap unlike ward plots – denoting comparable block sizes across cities. Table 1 gives total population, and percentage of SC, ST population. For purpose of this paper, we have combined SC and ST population – a standard practice in quantitative studies of urban segregation in India. Since only population numbers are made available at the enumeration block level, we are unable to study segregation based on socio-economic indicators (class variables), or do a comparative analysis of urban amenities in respective enumeration blocks.

We also use enumeration block maps of Bengaluru (we digitized and geo-registered ~16,00 polygons representing enumeration blocks and sub-blocks in Bengaluru’s 198 wards using official ward maps that we obtained from Census of India and merged block level population data) to present the first visual portrait of the extent of caste-based residential segregation in India.4

Table 1: City population and percentage of SCs and STs (Data from Census of India, 2011). Census numbers underestimate the number of people belonging to SC and ST groups. This is best illustrated by Delhi where census numbers report no person belonging to the ST group – which evidently does not reflect empirical reality. This discrepancy arises from the fact that Census uses state-specific SC and ST lists to tabulate group populations. Delhi does not have a state-specific ST list. People who belong to ST groups under lists from other states are not enumerated as ST in Delhi. Similar process is followed for enumeration of people belonging to SC groups as well. Thus for example, only people belonging to groups that are in the Karnataka SC list are counted under SC for the city of Bengaluru. A person belonging to an SC group that is recognized as such outside Karnataka is not enumerated as an SC in Bengaluru.

4 The Census of India does not make available digital files for census enumeration blocks. Cf. concluding section of this paper for our arguments about why future census operations must make geo-coded enumeration block data available in digital format.
Figure 3: Cumulative density plots of population at ward and block levels. Data from Census 2011. These plots provide the basis (or lack thereof) for comparisons across the five metro cities in India. The top panel shows the density plot at the ward level. Ward sizes are comparable across cities except Mumbai that has much larger wards. The block sizes (bottom panel) are comparable across all cities.
Measuring Segregation

We use a simple dissimilarity index and the standard Gini index to measure residential segregation. Both indices measure degree of `evenness' of a given geographical unit. The dissimilarity index measures how population shares of different social groups are different from the larger spatial aggregate. In our case, we ask how blocks in the ward are different from the ward itself as well as study how blocks are different from the city as a whole. To benchmark our block-level results with earlier ward-level results, and illustrate the extent of intra-ward segregation, we also present results for how wards in the city are different from city as a whole. Both the indices vary from 0 to 1, with 0 indicating complete integration; and 1, complete segregation.

We compute a simple Dissimilarity Index (D) at city and ward levels. We compute two different dissimilarity indices at the city-level, and one at the ward-level. At the city-level, we ask how the caste composition of a ward or a block is different from the city as a whole. To understand intra-ward heterogeneity, we also compute the dissimilarity index at the ward level – an indicator of how the blocks within a ward are different from ward as a whole. We use a simple index defined by:

\[ D = 0.5 \sum_{i=1}^{N} \frac{|s_i - r_i|}{S - R} \]

where \( s_i = \text{SC+ST population in } i^{th} \text{ block/ward} \)
\( S = \text{Total SC+ST population in ward/ city} \)
\( r_i = \text{Rest of the population } r^{th} \text{ block/ward} \)
\( R = \text{Rest of the population in ward/ city} \)

We also compute a simple Gini index as an index of segregation for each of the five cities that we study.

Gini index (G) of a city is calculated using:

\[ G = \frac{\sum_{i=1}^{n} \sum_{j=1}^{n} |s_i - s_j|}{2n \sum_{i=1}^{n} s_i} \]

where \( s_i \) and \( s_j \) are SC-ST populations in ward (or block) \( i \) and \( j \) respectively.

Results

Table 2 presents the three different dissimilarity indices that we compute in the paper. The first column reports the dissimilarity index computed at the ward-city level, and represents the benchmark result – for example, these numbers are consistent with numbers reported by Vithayathil & Singh (2012). As discussed, this index is a measure of how wards within a city are different in their caste composition from the city as a whole. The second column reports the dissimilarity index computed at the block-city level --- a measure of how the caste composition of blocks in a city are different from city as a whole. A comparison between these two columns illustrates how ignoring intra-ward segregation amounts to neglect of a significant portion of segregation in a city. The last two columns present a direct measure of intra-ward segregation. For each ward, we computed how the blocks within the ward are different from the ward as a whole in terms of caste composition. The table reports the median ward-block dissimilarity index for each city as well as a mean (ward population weighted).
In Figure 4, each of the six panels (corresponding to the five individual cities studied in this paper, and one corresponding to combined data from all the five cities) show two different SC-ST population Lorenz curves – one computed at the ward-level, and other computed at the block-level. For each of the five cities, the ward-level Lorenz curve lies unambiguously, and wholly inside the block-level Lorenz curve. The degree of intra-ward heterogeneity is seen from the difference in Gini coefficients at block and ward levels. The Gini coefficients reported here are a measure of segregation at ward and block levels. This figure clearly illustrates why treating ward as a homogenous entity is empirically fraught. For example, in Bengaluru, there is a 30% difference between segregation measured at block and ward levels as measured by the Gini index.

Figure 5 illustrates how there is no systematic relationship between ward size and the dissimilarity index. The first panel in the figure combines wards from all five cities that we study in this paper. This figure provides evidence for intra-ward heterogeneity across ward sizes. Figure 6 illustrates the extent of intra-ward heterogeneity. For each of the five cities, as well as for the combined dataset, we present the distribution of the block-ward dissimilarity index.

Figure 7 juxtaposes kernel density plots for fractionalization index computed at block and ward levels for each of the five cities (the first panel combines blocks and wards from all five cities). Even when wards are diverse (higher fractionalization), the blocks are homogenous (lower fractionalization). The fractionalization index is usefully interpreted as the probability that two randomly selected people (here, from either a ward or a block) belong to different social groups (here either SC-ST or OTH).

Visualizing Quantitative Segregation Results: The Case of Bengaluru
We illustrate the quantitative results from the section spatially using Bangalore as our case.
study. Considered as the IT hub of India, Bengaluru (also known as Bangalore) is a great example of changes which economic liberalisation can bring about in the form and fabric of a city. In 2011 the number of foreign investment projects in the city was eighth highest in the world (Fingar, 2013). Bangalore was founded in the 1537 by Kempegowda, a local chieftain. At the time of Kempegowda, the city was divided into several *petes*—each one for different trades and profession—which was similar to any other traditional Indian city. Since trades and professions were based on caste system, we can say that the city was divided along caste lines. Nagarthpete was for textile and gold traders, Ganigarapete was for *Ganigas*—the oil pressing caste, Cubbonpete—was for people of the Devanga community who were the weavers of traditional silk sarees, Kumbarapete for potters, Upparapete was for the members of the *Uppara* caste, Thigalarapete was for *Thigalas* and so on (Nair, 2005). After the British captured the city in 1791, the documents show that the city was divided and organised along caste lines (Buchanan, 1807).

When the British settled in Bangalore, they chose not to have any connections with the existing city and started a new military settlement—Cantonment in 1809 far from the existing settlement. This settlement was a complete different society as compared to then existing Bangalore city. The population of the Cantonment consisted of Europeans and the people from Madras state. It took more than a century for these two different cities to merge. Even today, the difference between these two parts of the city is quite felt in terms of culture, language and landscape.

During World War II and after independence various public-sector industries were started in Bangalore that resulted in migration from other parts of India. Noel Gist (1958) in his study of Bangalore notes that there were some neighbourhoods in the city where a large number of families belonging to depressed classes lived. He also notes that areas of highest occupancy by depressed castes were on or near the city’s outskirts. He observes that members of Brahmin caste showed similar tendencies of segregated residence. Brahmins were concentrated in the western part of the city and the areas occupied heavily by Brahmans and other high caste Hindus were attractive residential districts, among the most sought after as the city grew. Muslims were highly segregated and lived in highly congested neighbourhoods. Majority of the Christians lived in Cantonment, and among them Anglo-Indians lived separately. He concludes that spatial isolation of various communities reflected their social isolation.

Economic liberalisation brought about profound changes in the economy of the city. During the 1990s, Bangalore was a preferred location for many Information technology (IT) related industries and Bangalore emerged as a globally integrated centre of high-technology research and production (Dittrich, 2007). This boom in economy created enormous employment opportunities and allied service sector grew at a faster pace. As a result, Bangalore became one of the fastest growing cities in India in terms of population and geographical area. Bangalore urban district’s population grew at a whopping rate of 46.68 per cent over the past decade (2001-2011) as compared to 7.65 per cent growth of Chennai and 4.2 per cent growth rate of Mumbai. That makes Bangalore the fastest growing city in India. This has changed the demography and geography of the city. The socio-cultural dynamics and the urban settlement patterns have had a momentous change (Dittrich, 2007).

We use EB level maps of Census 2011 to study the intra-ward level residential segregation in Bangalore. Figure 10 illustrates the spatial variation of SC-ST population in Bangalore. As we can notice, there are many neighborhoods (EBs) with no SC-ST population and neighborhoods with substantial SC-ST population denoting highly segregation. Figure 11 zooms in on a particular portion of Figure 10 to better illustrate intra-ward variation in SC+ST populations.

Figure 8 Bengaluru enumeration block level SC+ST population variation. The population numbers, ward boundaries, and block boundaries are all from Census of India (2011). Also cf. Figure-11
Figure 9: Variation of SC+ST population within wards in Bengaluru. This figure zooms in on a particular portion of Figure-10 to better illustrate intra-ward variation in SC+ST populations. As we can notice, within a ward, there can be blocks with no SC+ST population and blocks with substantial SC+ST population. This illustrates how neighborhoods within ward are highly segregated and studies on segregation at ward level amounts to neglect of a significant portion of segregation in a city.

Conclusion

We presented the first ever neighbourhood-scale segregation patterns in India’s major urban centres, and in the case of Bengaluru, the first visual map of neighbourhood-scale segregation of space by caste. Our analysis provides the first ever systematic neighborhood-scale evidence for urban segregation in India – in a discourse dominated by anecdotal accounts of ethnic space making in urban India. Our analysis immediately point to severe data limitations that has constrained scholarship, policy, and praxis surrounding urbanization. The results of this paper make a strong case for future census data to be released at a geo-tagged enumeration block resolution. The project team collectively spent over 90 full time person days to digitize and geo-reference block level data -- effectively replicating digital data that the Census of India does not make public. If an analog version is made public, there is no reason why a digital version should not also be made public. Currently, the Census of India releases enumeration block level data for only basic population numbers that does not permit characterizing segregation based on other socio-economic axes, or characterize the uneven availability of public goods in different neighbourhoods. By developing a visual portrait of segregation for Bengaluru, this paper has demonstrated that enumeration block data must become the bedrock for any policy and praxis focused on building inclusive urban spaces.

While our analysis provides the most detailed portrait to date of spatial segregation in urban India, our snapshot provides little insights into the causal pathways that can explain the linkages between urbanization and ethnic space making. A significant limitation of the portrait we have presented here is that we have not been able to control for non-ethnic characteristics of the neighborhoods. For example, we do not know if the pattern of social segregation of space that we have presented here holds across economics classes since enumeration block level neighborhood amenities, education, data is not public. Data limitations also prevent us from studying residential segregation along religious lines.

Data limitations notwithstanding, our results pose a significant challenge to one of the bedrock normative promises of urbanization in India – the dilution of caste boundaries Indian cities (at least
the cities presented in the paper, and there is no reason to believe the results will be very different in other urban centres) remain highly segregated along caste lines. Thus, studying patterns of urban segregation offers an important window to understanding the robust perseverance of caste structures in contemporary India.
